

Chapter 11

Convergence of Nanotechnology and Microbiology

Mussrat Fayaz Khanday
Annamalai University, Tamil Nadu, India

ABSTRACT

The convergence of nanotechnology with microbiology is a nifty interdisciplinary research area that could amplify the limits of technology, enhance global health through formation of different drugs that can be effective against different infectious diseases, and for treatment of drinking water to kill the pathogens and make it safe for public use. Bacteria, fungi, actinomycetes, and plants have been successfully used for the formation of nanoparticles of silver, gold, zinc, etc. As the microorganisms, especially bacteria, are becoming resistant to the commonly used antibiotics, an alternative antimicrobial agent that can be effective against the antibiotic-resistant bacteria is needed. In the present chapter, the author highlights the relationship between these two mighty disciplines. The chapter deals with many aspects like antimicrobial activity of nanoparticles, formation of nanoparticles using microorganisms, etc. The green synthesis of nanoparticles is emerging as a new field of science; hence, it is discussed in detail.

INTRODUCTION

Nanotechnology is emerging as one of the leading subject of interest for researchers. Nanoparticles preparation and application in various fields like catalysis, electronics, environmental, pharmaceutical and biotechnology has been expanded significantly. Microbiology relates to nanotechnology at number of levels. It is well known that many organisms can produce inorganic materials either intra or extracellularly. For example, unicellular organisms such as magnetotectic bacteria produce magnetic nanoparticles and diatoms synthesize siliceous materials. Many bacterial entities are nano-machines in nature, including molecular motors like flagella & pilli. Bacteria also form biofilms by the process of self-assembly (e.g the formation of curli film by *E.coli*). Nanotechnology can be used to study the process of biofilm formation, a key medical problem. It can also be used to study the self-assembly of viral capsids as we desperately need anti-viral drugs.

World is facing a new problem of water scarcity. The availability of drinking water is decreasing rapidly due to water pollution and climatic change. Microorganisms like bacteria viruses and protozoa are a great threat to the available fresh water resources. These organisms can contaminate the water bodies resulting in different kind of water born diseases like cholera hepatitis etc. overcoming this challenge is becoming increasingly difficult as the demand of safer water grows with the increasing in world population and climate change threatens to take away a large fraction of already scarce fresh water. Nanotechnology can enable both safer and sustainable solutions to these problems. By the help of nanotechnology we can develop new processes and enhance the performance of existing treatment process. Nanotechnology can address emerging disinfection challenges to make water safe for consumption (e.g., photocatalytically enhanced disinfection, biofouling-resistant membranes, biofilm and corrosion-resistant surfaces, and sensors for pathogen detection)

Bacteria which are not exposed to large concentrations of metal ions may also be used to synthesize nanoparticles. It has long been reported that among the eukaryotes yeasts are explored mostly in the biosynthesis of semiconductor nanoparticles. Fungi have also been used for the synthesis of nanoparticles. The use of fungi is potentially excited since they secrete large amounts of enzymes and simpler to deal with in the laboratory.

Biosynthesis of nanoparticles from plants, bacteria, fungi is gaining interest as the process is less time consuming and economical compared to chemical synthesis. Many bacteria have been successfully used for the preparation of gold, silver, zinc and other nanoparticles. Biologically synthesized nanoparticles are being widely used in the field of medicine. For the last two years extensive work has been done to develop new drugs from natural products because of the resistance of microorganisms to the existing drugs.
