## **Abstract**

*Realisation of the Ubicomp vision in the real world creates significant threats to personal privacy due to constant information collection by numerous tiny sensors, active information exchange over short and long distances, long-term storage of*

*large quantities of data, and reasoning based on collected and stored data. An analysis of more than 100 Ubicomp scenarios, however, shows that applications are often proposed without considering privacy issues, whereas existing privacy-enhancing technologies mainly have been developed for networked applications and, thus, are not always applicable to emerging applications for smart spaces and personal devices, especially because the users and their data are not spatially separated in such applications. A partial solution to the problem of users' privacy protection could be to allow users to control how their personal data can be used. The authors' experience with mobile phone data collection, nevertheless, suggests that when users give their consent for the data collection, they don't fully understand the possible privacy implications. Thus, application developers should pay attention to privacy protection; otherwise, such problems could result in users not accepting Ubicomp applications. This chapter suggests guidelines for estimating threats to privacy, depending on real world application settings and the choice of technology; and guidelines for the choice and development of technological safeguards against privacy threats.*

## Introduction

---

After having read a large number of scenarios of emerging Ubicomp applications (found in project deliverables and research publications which describe prototypes of smart spaces, smart personal devices, objects and their functionalities) and visionary future Ubicomp scenarios (found mainly in roadmaps), we concluded that most scenarios present a sunny, problem-free vision of our future. With the exception of the surveillance problem in some cases, most scenarios do not consider the privacy issues that the new technologies are likely to raise. For example, they do not discuss possible privacy problems due to conflicts between people's interests or personal curiosity.

The discovery that Ubicomp technologies raise privacy problems is not new; and research into privacy protection is actively going on, but after a state-of-the-art review of work on privacy protection, we have come to the conclusion that most of this work deals with privacy protection in such network applications as m-commerce, Web browsing, virtual meetings, location-based services, and so forth, where users can be physically separated from their personal data. Even in these applications, no scalable solutions fully applicable in real life exist, and this lack of protection allows large-scale eavesdropping, as we know from the news (Web site of the American Civil Liberties Union and the ACLU Foundation, 2006).

The work on privacy protection in smart spaces and in connection with personal devices is even less mature than that concerned with network applications, while
